Term Start Presentation

Project motivation, problem definition, proposed scope, and initial plan.

Design and Development of a Web Platform for Cross-Cultural Opinion Analysis

Prepared by: [Student Name] | May 1, 2026

Agenda

- 1 Problem context and motivation
- 2 Target users and expected value
- 3 Initial scope and out-of-scope boundaries
- 4 Planned architecture, data, security, and timeline
- 5 Risks, assumptions, and success criteria

Problem

- Online polls often show only global totals and hide cultural differences.
- Large scientific surveys are rigorous but slow and not interactive.
- Controversial topics need transparent statistics, discussion, and abuse protection.
- The project explores a practical middle ground: fast web participation with country-aware comparison.

Motivation

Opinion platforms need context, not only totals.

- A 51 percent result can mean very different things when countries, age bands, and discussion context are visible.
- A web prototype can make comparative thinking easier, even when it cannot replace scientific sampling.
- The engineering challenge is to combine participation, analysis, security, and privacy in one coherent flow.

Project Aim

- Build a web platform where users vote on controversial questions.
- Display option, country, age, and gender distributions.
- Support country-to-country comparison for the same question.
- Allow comments, replies, likes, profiles, categories, and leaderboards.

Initial User Roles

- Visitor: browse public questions, categories, leaderboards, and stats.
- Registered user: vote, comment, like, manage profile, and view AI summaries.
- Administrator: create categories, import questions, publish, archive, and inspect content.

Scope Boundaries

Included in the Thesis Prototype

- Question browsing and authenticated voting
- Country, age, gender, and option statistics
- Comments, replies, likes, and AI summary
- Admin question and category management

Deferred Beyond the Prototype

- Representative national sampling
- Payment, advertising, or public API monetization
- Full moderation operations center
- Native mobile applications

Planned Technology Stack

- .NET 8 ASP.NET Core Web API for backend services.
- React, TypeScript, Vite, React Query, and Tailwind CSS for frontend.
- PostgreSQL for relational data and Redis for cache/rate limiting.
- Docker Compose for local and production-like deployment.
- Gemini integration for AI-assisted summaries.

Expected Architecture

Initial Requirement Map

Requirement	Why It Matters	Expected Evidence
Authenticated voting	Limits duplicate participation and supports profile-based analysis.	Vote flow, token validation, cooldown checks
Country comparison	Makes cross-cultural differences visible.	Country pair modal and global baseline
Abuse protection	Protects quality of vote and comment signals.	Redis counters and request limits
Documentation	Supports academic review and reproducibility.	Thesis, slides, guide, install PDF

Initial Risks

- Country inference can be inaccurate for VPN/proxy traffic.
- Self-selected users do not produce representative survey samples.
- Spam and repeated actions can distort vote and comment signals.
- Opinion data can be sensitive and requires privacy-aware design.

Project Plan

1

Phase 1

Authentication, question model, category model, and basic vote flow.

2

Phase 2

Statistics, country comparison, comments, replies, and profiles.

3

Phase 3

Admin tools, Redis limits, AI summaries, privacy pages, and consent.

4

Phase 4

Docker deployment, final documentation, verification, and demo preparation.

Success Criteria

- A user can register, log in, vote, inspect statistics, and participate in discussion.
- An administrator can create, import, publish, archive, and organize questions.
- The system avoids raw IP storage and separates analytics consent from core usage.
- The final documentation explains installation, usage, design, limitations, and license information.
